## Abstract

We describe an algorithm for computing AM response of interferometers. This algorithm is based on previous work by Livas (Liv) and [1] Schutz and Tinto (ST) [2]. Comparisons with work by ST, and Anderson, Brady, and Creighton (ABC) [3] is made.

## Goals

- compute the Amplitude Modulation response of any given interferometer to polarized sources of gravitational radiation
- implement for the LAL

## Strategy

- follow Livas [1] and Schutz & Tinto [2].
- express the metric perturbation tensor,  $h_{\mu\nu}$ , in the basis of the Detector frame, and compute the sensitivities
- ignore orbital parallax, nutation of the Earth's rotation, and most other irregularities
- *don't* ignore the tilt of the plane of the IFO, which will be equivalent to an effective location different from the location of the IFO vertex
- ∴ the coordinate transformations reduce to a series of (Euler) rotations.

- sensitivities are given by Schutz & Tinto [2]:

$$F_+ = -\sin 2\beta [A_X^x A_X^y - A_Y^x A_Y^y]$$

$$F_\times = \sin 2\beta [A_X^x A_Y^y + A_Y^x A_X^y]$$

$$\delta l/l_0 = F_+ h_+ + \exp(i\delta) F_\times h_\times$$

where

$A$  = the transformation matrix

$\beta$  = half the angle between the arms

$\delta$  = phase difference between the +  
and the  $\times$  polarizations

$\delta l$  = difference between the values of  
 $\delta l_n, n = 1, 2$  for the two arms

# Coordinate Conventions

- define conventions for the coordinate axes of the reference frames of the source, and the interferometer
- Source reference frame has  $Z$ -axis pointing from the source *to* the observer; orientations measured relative to meridians (lines of constant RA), *i.e.* w.r.t. equatorial coordinates

- view from the IFO location to the source would look like:

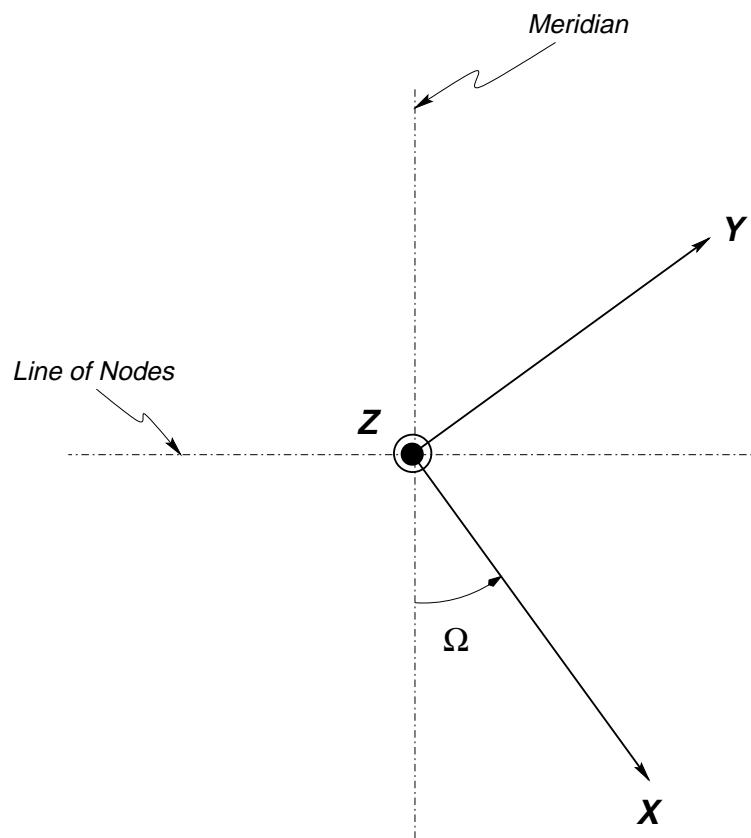

Figure 1: Source Frame

- Source position is given in RA-dec, orientation is measured w.r.t. meridian

- Detector reference frame has  $Z$ -axis pointing to its zenith, *i.e.* perpendicular to the plane of the detector
- the plan view of the Detector frame would be:

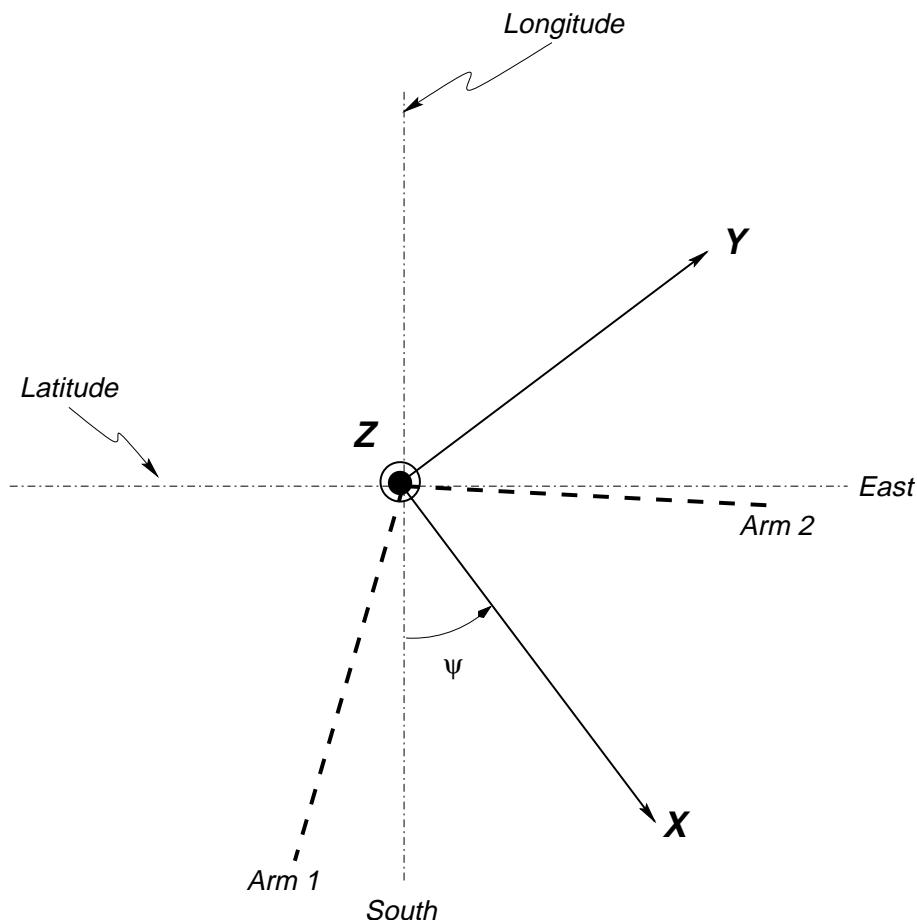

Figure 2: Detector Frame

- NB: orientation angle is measured East of South (counter-clockwise) to the bisector of the arms, as per convention in Schutz & Tinto [2].
- tilt of detector is taken into account by making two additional rotations using LIGO survey data [4]

## Coordinate Conventions: Schutz & Tinto

- in Section 2 of Schutz and Tinto's paper [2], they compute the single-detector response function
- their convention for the Source orientation is made relative to the vertical circle of the IFO, *i.e.* w.r.t. horizon coordinates
- vertical circle is the circle that passes through the IFO's zenith and the Source: it is not necessarily a meridian
- position of Source is given as altitude-azimuth, and orientation is measured w.r.t. vertical circle
- this is already implicitly in the Detector frame

## Coord. Conventions: Anderson, et al.

- Source frame has  $Z$ -axis pointing from Source to Earth.
- Source position is given as RA-dec; orientation is measured w.r.t. Line of Nodes (see Fig. 1)
- IFO frame and orientation are derived by differential geometry using Earth model ellipsoid WGS-84, and LIGO survey data [4]

## Euler Rotations

- make Euler rotations about the  $Z$ - and  $Y$ -axes.
- form of these rotation matrices:

$$R_z(\theta) = \begin{pmatrix} \cos \theta & \sin \theta & 0 \\ -\sin \theta & \cos \theta & 0 \\ 0 & 0 & 1 \end{pmatrix}$$
$$R_y(\theta) = \begin{pmatrix} \cos \theta & 0 & -\sin \theta \\ 0 & 1 & 0 \\ \sin \theta & 0 & \cos \theta \end{pmatrix}$$

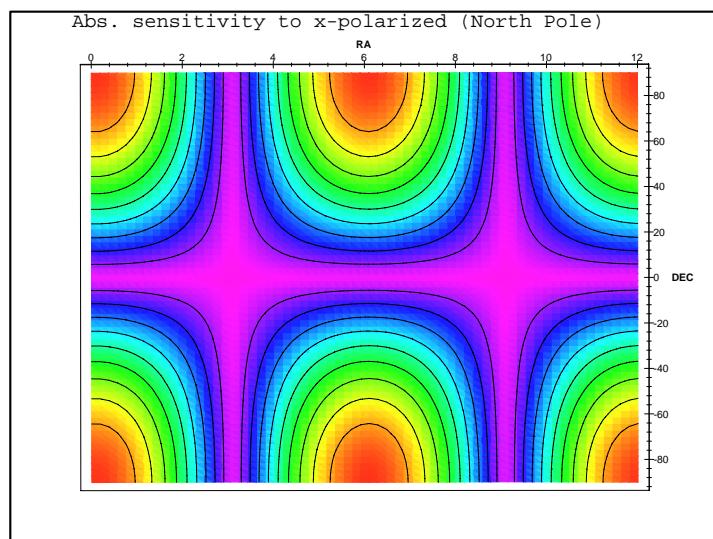

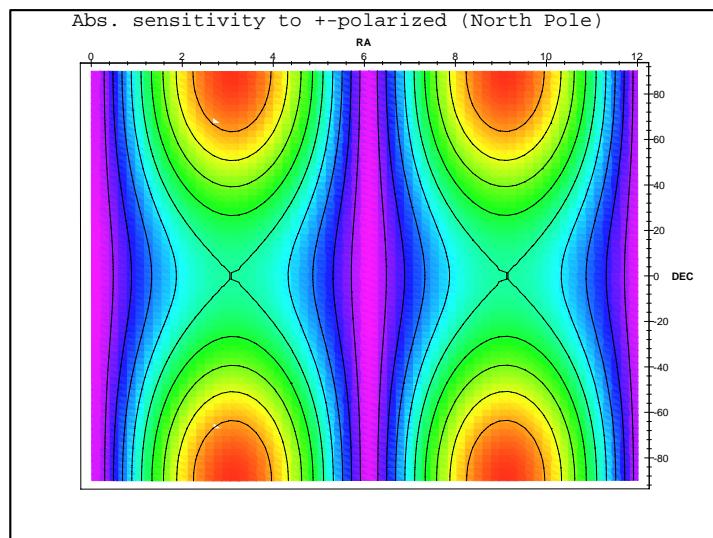

- total transformation is a product of rotations:

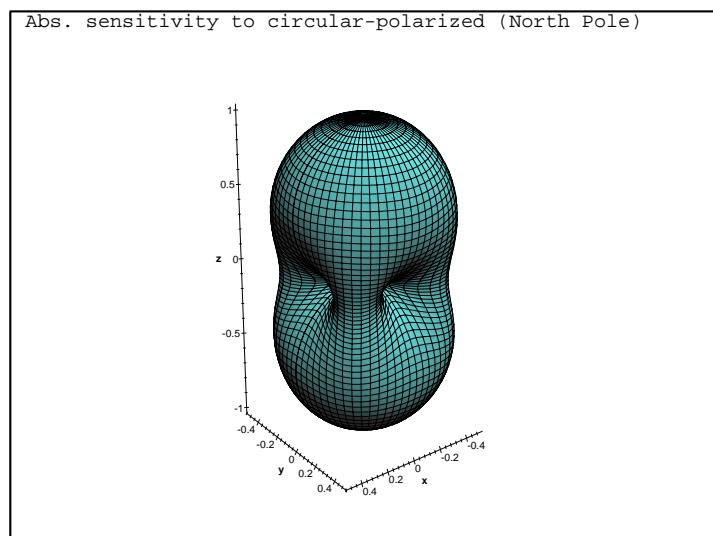

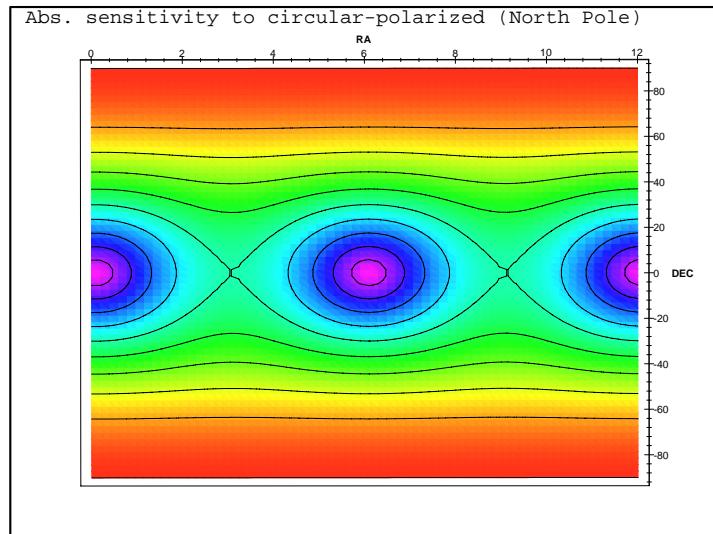

$$\begin{aligned}
 R &= R_z(\psi)R_y\left(\frac{\pi}{2} - lat\right)R_z(LMST) \\
 &\quad R_z(\pi - RA)R_y\left(-\left(\frac{\pi}{2} + dec\right)\right)R_z(-\Omega)
 \end{aligned}$$

where

- $\psi$  = orientation angle of IFO
- $lat$  = latitude of IFO
- $LMST$  = Local Mean Sidereal Time
- $dec$  = declination of Source
- $\Omega$  = orientation of Source

# Plots of Response (Dec. vs. RA; Detector @ North Pole)

## Comparison Tests: Single Point

- compare results from the three different algorithms for special source location and orientation, and sidereal time

## Related Packages: Date and Time

- date and time utility routines have been coded into LAL package: part of LAL beta-0.4 release
- converts time to and from seconds from GPS epoch and seconds from Unix epoch
- converts time in seconds from some epoch to time structure with day, date, residual nanoseconds, etc.

## Future Refinements

- vector routine: given initial time, size of time step, and number of time steps, returns vector containing response at each of those time steps
- standardized IFO description parameter data structures, coordinated with J. Romano (UT-Brownsville)
- detailed documentation (LIGO tech note) in preparation

## Acknowledgements

We thank W. Anderson, P. Brady, and J. Creighton  
for sharing their Maple worksheet
